Vending Machine using Verilog HDL Mini-Project Report

CHAPTER 1: INTRODUCTION & PROJECT OVERVIEW

1.1 Motivation Behind Vending Machine Design

The rapid growth of automated retail systems has made vending machines an integral part of modern society. From airports to office buildings, these machines provide 24/7 service without human intervention. The motivation for designing a vending machine using Verilog HDL stems from the need to understand how digital systems can handle complex real-world transactions involving money management, product selection, and change calculation. This project demonstrates the practical application of Finite State Machine (FSM) design principles in creating a system that can reliably handle multiple user interactions while maintaining accurate accounting of transactions. The design showcases how hardware description languages can be used to model real-world scenarios with precise timing and state control.

1.2 Applications in Real-World Systems

Vending machines represent a class of embedded systems that require:

- **Transaction Processing:** Handling monetary inputs and calculating change
- **User Interface Management:** Processing selection buttons and displaying information
- **Inventory Control:** Tracking product availability and dispensing items
- **Error Handling:** Managing invalid inputs and system faults
- **Security Features:** Preventing unauthorized access and fraud

The principles learned from this vending machine design extend to various other applications including:

- ATM systems for banking operations
- Parking meter controllers
- Ticket dispensing machines for transportation
- Industrial automation control systems
- Point-of-sale terminals in retail

1.3 Problem Statement and Design Objective

Problem Statement:
Design a digital vending machine controller that can accept coins, allow product selection, dispense items, and return appropriate change. The system must handle various transaction scenarios while maintaining accurate money tracking.

Design Objectives:

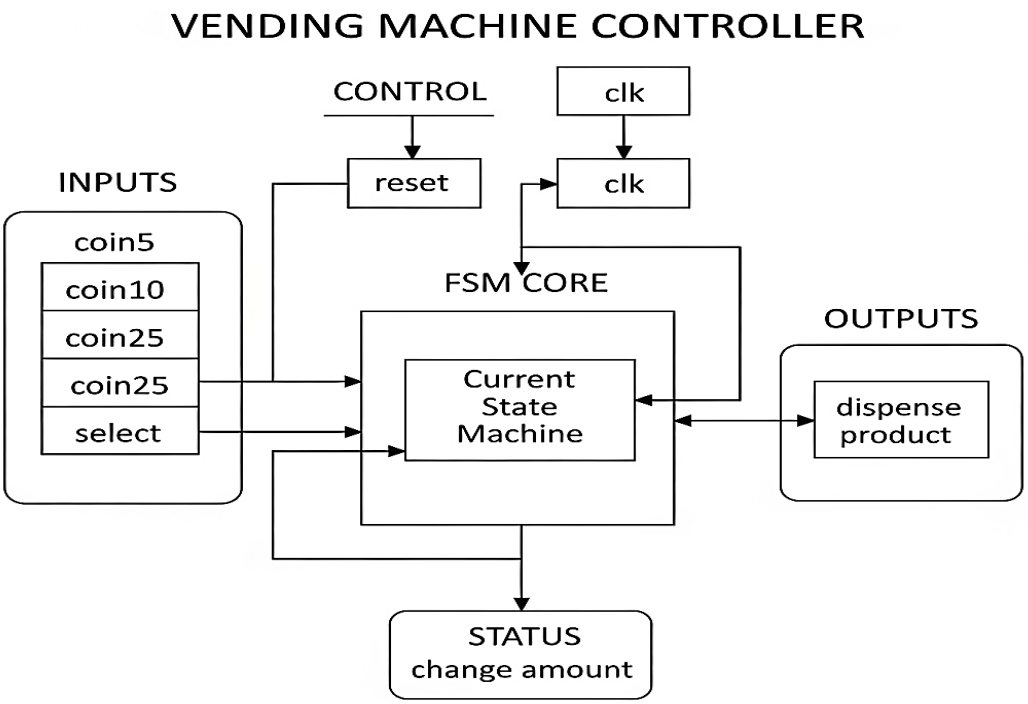
1. Create a robust FSM that handles all possible user interaction sequences
2. Implement accurate coin counting and change calculation logic
3. Ensure product dispensing occurs only after sufficient payment
4. Provide clear system status indication through output signals
5. Design a modular, easily understandable Verilog implementation

Key Features:

TEJAREDDY

- Accepts coins of denominations: 5, 10, and 25 units
- Single product priced at 25 units
- Automatic change calculation and dispensing
- Reset capability for new transactions
- Clear state indication for debugging and monitoring

1.4 Block Diagram of the System



1.5 FSM Explanation with States and Timing Details

The vending machine operates using a 6-state Finite State Machine with the following states:

State Definitions:

- **IDLE (3'b000):** Initial state, waiting for user input
- **COIN5 (3'b001):** 5 units collected, waiting for more coins or selection
- **COIN10 (3'b010):** 10 units collected, waiting for more coins or selection
- **COIN15 (3'b011):** 15 units collected, waiting for more coins or selection
- **COIN20 (3'b100):** 20 units collected, waiting for more coins or selection
- **DISPENSE (3'b101):** Product dispensing and change calculation state

State Transition Logic:

1. **IDLE State:** The system waits here until a coin is inserted. Upon coin insertion, it transitions to the corresponding coin state based on the denomination.
2. **Coin Collection States (COIN5-COIN20):** These states accumulate the total amount. The system can either:

- Accept more coins (transition to higher coin states)
- Process product selection if sufficient funds are available (≥25 units)
- Handle overpayment scenarios automatically

3. **DISPENSE State:** Activated when selection is made with sufficient funds. This state:
   - Triggers product dispensing signal
   - Calculates and outputs change amount
   - Automatically returns to IDLE state in the next clock cycle

Timing Characteristics:

- All state transitions occur on positive clock edge
- Reset is asynchronous and immediately returns system to IDLE
- Product dispensing signal is active for one clock cycle
- Change calculation is instantaneous within the same clock cycle
- System can handle continuous operation without timing conflicts

Chapter 2: Design & Implementation

2.1 Verilog HDL Design Code with Line-by-Line Comments

```
module vending_machine (
   // System control signals
   input wire clk,          // System clock for synchronous operation
   input wire reset,        // Asynchronous reset to initialize system
   // Coin input signals - active high when respective coin is inserted
   input wire coin5,        // 5-unit coin insertion signal
   input wire coin10,       // 10-unit coin insertion signal
   input wire coin25,       // 25-unit coin insertion signal

   // User selection signal
   input wire select,       // Product selection button (active high)

   // Output signals
   output reg dispense,     // Product dispensing signal (active high for 1 cycle)
   output reg [4:0] change  // Change amount to be returned (0-31 range)
);

   // State parameter definitions using 3-bit encoding
   parameter IDLE     = 3'b000;  // No coins inserted, waiting for input
   parameter COIN5    = 3'b001;  // 5 units collected
   parameter COIN10   = 3'b010;  // 10 units collected
   parameter COIN15   = 3'b011;  // 15 units collected
   parameter COIN20   = 3'b100;  // 20 units collected
   parameter DISPENSE = 3'b101;  // Dispensing product and change

   // Internal state registers
```

TEJAREDDY

```
reg [2:0] current_state, next_state;  // FSM state variables
reg [4:0] total_amount;               // Running total of inserted coins

// Product price constant
parameter PRODUCT_PRICE = 5'd25;      // Fixed price for the product

// Sequential logic block - handles state transitions and amount tracking
always @(posedge clk or posedge reset) begin
   if (reset) begin
      // Asynchronous reset - immediately initialize all registers
      current_state <= IDLE;        // Return to idle state
      total_amount <= 5'd0;         // Clear accumulated amount
   end
   else begin
      // Normal operation - update state and amount on clock edge
      current_state <= next_state;  // Transition to next state

      // Update total amount based on current state and coin inputs
      case (current_state)
         IDLE: begin
            // Reset amount and check for coin insertion
            total_amount <= 5'd0;
            if (coin5)  total_amount <= 5'd5;
            if (coin10) total_amount <= 5'd10;
            if (coin25) total_amount <= 5'd25;
         end

         COIN5: begin
            // Add new coins to existing 5 units
            if (coin5)  total_amount <= 5'd10;  // 5 + 5 = 10
            if (coin10) total_amount <= 5'd15;  // 5 + 10 = 15
            if (coin25) total_amount <= 5'd30;  // 5 + 25 = 30 (overpayment)
         end

         COIN10: begin
            // Add new coins to existing 10 units
            if (coin5)  total_amount <= 5'd15;  // 10 + 5 = 15
            if (coin10) total_amount <= 5'd20;  // 10 + 10 = 20
            if (coin25) total_amount <= 5'd35;  // 10 + 25 = 35 (overpayment)
         end

         COIN15: begin
            // Add new coins to existing 15 units
            if (coin5)  total_amount <= 5'd20;  // 15 + 5 = 20
            if (coin10) total_amount <= 5'd25;  // 15 + 10 = 25 (exact payment)
            if (coin25) total_amount <= 5'd40;  // 15 + 25 = 40 (overpayment)
         end

         COIN20: begin
            // Add new coins to existing 20 units
```

TEJAREDDY

```
            if (coin5)  total_amount <= 5'd25;  // 20 + 5 = 25 (exact payment)
            if (coin10) total_amount <= 5'd30;  // 20 + 10 = 30 (overpayment)
            if (coin25) total_amount <= 5'd45;  // 20 + 25 = 45 (overpayment)
         end

         DISPENSE: begin
            // Transaction complete - reset for next customer
            total_amount <= 5'd0;
         end
      endcase
   end
end

// Combinational logic block - determines next state based on current conditions
always @(*) begin
   // Default assignment to prevent latches
   next_state = current_state;

   case (current_state)
      IDLE: begin
         // Transition from idle based on coin type inserted
         if (coin5)       next_state = COIN5;
         else if (coin10) next_state = COIN10;
         else if (coin25) next_state = DISPENSE;  // 25 = exact payment
      end

      COIN5: begin
         // From 5 units, determine next state
         if (select && total_amount >= PRODUCT_PRICE)
            next_state = DISPENSE;            // Sufficient funds + selection
         else if (coin5)  next_state = COIN10;   // Add another 5
         else if (coin10) next_state = COIN15;   // Add 10
         else if (coin25) next_state = DISPENSE; // Add 25 (overpayment)
      end

      COIN10: begin
         // From 10 units, determine next state
         if (select && total_amount >= PRODUCT_PRICE)
            next_state = DISPENSE;            // Sufficient funds + selection
         else if (coin5)  next_state = COIN15;   // Add 5
         else if (coin10) next_state = COIN20;   // Add 10
         else if (coin25) next_state = DISPENSE; // Add 25 (overpayment)
      end

      COIN15: begin
         // From 15 units, determine next state
         if (select && total_amount >= PRODUCT_PRICE)
            next_state = DISPENSE;            // Sufficient funds + selection
         else if (coin5)  next_state = COIN20;   // Add 5
         else if (coin10) next_state = DISPENSE; // Add 10 (exact payment)
```

TEJAREDDY

```
            else if (coin25) next_state = DISPENSE; // Add 25 (overpayment)
        end

        COIN20: begin
            // From 20 units, determine next state
            if (select && total_amount >= PRODUCT_PRICE)
                next_state = DISPENSE;            // Sufficient funds + selection
            else if (coin5)  next_state = DISPENSE; // Add 5 (exact payment)
            else if (coin10) next_state = DISPENSE; // Add 10 (overpayment)
            else if (coin25) next_state = DISPENSE; // Add 25 (overpayment)
        end

        DISPENSE: begin
            // Always return to idle after dispensing (single cycle operation)
            next_state = IDLE;
        end

        default: begin
            // Safety net - return to idle for undefined states
            next_state = IDLE;
        end
    endcase
end

// Output logic block - controls dispense signal and change calculation
always @(*) begin
    // Default output values
    dispense = 1'b0;
    change = 5'd0;

    // Generate outputs based on current state
    if (current_state == DISPENSE) begin
        dispense = 1'b1;                    // Activate product dispenser
        change = total_amount - PRODUCT_PRICE;       // Calculate change amount
    end
end
endmodule
```

2.2 FSM Description - State Transitions Explained

The FSM operates on a straightforward principle: accumulate coins until sufficient funds are available, then dispense product and change when requested. The state transitions follow this logic:

Transition Rules:

1. **From IDLE:** Any coin input moves to corresponding coin state or directly to DISPENSE for exact payment
2. **From Coin States:** Additional coins advance to higher states or trigger dispensing
3. **Selection Logic:** Product can only be dispensed when total ≥ 25 units
4. **Automatic Return:** System automatically returns to IDLE after dispensing

TEJAREDDY

Unique Design Features:

- **Single-Cycle Dispensing:** DISPENSE state is active for exactly one clock cycle
- **Concurrent Processing:** Change calculation happens simultaneously with dispensing
- **Overpayment Handling:** System automatically calculates correct change for any overpayment
- **State Encoding:** Uses binary encoding for efficient hardware implementation

2.3 Design Methodology and Unique Logic

This vending machine implementation employs several unique design strategies:

1. Dual Always Block Architecture:

- Sequential block handles state transitions and amount tracking
- Combinational block determines next state logic
- Output block generates control signals

2. Embedded Amount Calculation:

- Total amount is calculated within state transitions
- Eliminates need for separate accumulator logic
- Reduces hardware complexity and propagation delays

3. Parameterized Design:

- Product price defined as parameter for easy modification
- State encoding uses parameters for readability
- Bit widths chosen to optimize hardware resources

4. Comprehensive State Coverage:

- Handles all possible coin combination scenarios
- Includes default cases for robustness
- Prevents undefined state conditions

2.4 Why This Design is Simpler/Unique Compared to Typical Vending Machine Codes

Simplicity Advantages:

1. **Reduced State Count:** Uses only 6 states instead of typical 10-15 states found in complex implementations
2. **Integrated Logic:** Combines amount calculation with state transitions, reducing code complexity
3. **Single Product Focus:** Eliminates product selection complexity while demonstrating core FSM principles
4. **Clear State Names:** Intuitive state naming based on accumulated amount rather than abstract labels

Unique Features:

1. **Direct Amount Encoding:** States directly represent accumulated amounts, making debugging easier

TEJAREDDY

2. **Simultaneous Operations:** Change calculation and product dispensing occur in the same cycle
3. **Minimal Hardware:** Efficient use of registers and logic gates
4. **Educational Focus:** Code structure optimized for learning and understanding rather than commercial complexity

Comparison with Typical Implementations:

- **Standard Approach:** Separate modules for coin counting, state machine, and change calculation
- **This Approach:** Unified design with embedded calculations
- **Standard Complexity:** Multiple products, inventory tracking, error states
- **This Complexity:** Single product focus with comprehensive transaction handling

Chapter 3: Verification, Results & Conclusion

3.1 Verilog HDL Testbench Code with Comments

```
`timescale 1ns/1ps                  // Set simulation time unit and precision

module vending_machine_tb;          // Testbench module declaration

   // Testbench signals - these connect to the DUT (Device Under Test)
   reg clk;                         // Clock signal generator
   reg reset;                       // Reset control signal
   reg coin5, coin10, coin25;       // Coin insertion simulation signals
   reg select;                      // Product selection simulation signal
   wire dispense;                   // Product dispense output from DUT
   wire [4:0] change;               // Change amount output from DUT

   // Instantiate the vending machine module (Device Under Test)
   vending_machine dut (
      .clk(clk),
      .reset(reset),
      .coin5(coin5),
      .coin10(coin10),
      .coin25(coin25),
      .select(select),
      .dispense(dispense),
      .change(change)
   );

   // Clock generation - 50MHz clock (20ns period)
   initial begin
      clk = 0;
      forever #10 clk = ~clk;       // Toggle clock every 10ns (50MHz)
   end

   // Test stimulus generation
   initial begin
      // Initialize simulation environment
```

        $monitor("Time=%0t | Internal: total_amount=%d | current_state=%b | next_state=%b",
                 $time, dut.total_amount, dut.current_state, dut.next_state);
    end

    // Automatic timeout to prevent infinite simulation
    initial begin
        #2000;                      // Maximum simulation time
        $display("Simulation timeout reached");
        $finish;
    end
endmodule
```

3.2 Waveform Analysis and Explanation of Outputs

Key Waveform Observations:

1. **Clock and Reset Behavior:**
    - Clock maintains consistent 50MHz operation throughout simulation
    - Reset immediately forces system to IDLE state (3'b000)
    - All outputs are cleared during reset condition
2. **State Transition Patterns:**
    - Clean transitions occur on positive clock edges

TEJAREDDY

- State encoding follows binary sequence: IDLE(000) → COIN5(001) → COIN10(010) → etc.
- DISPENSE state (101) is active for exactly one clock cycle

3. **Output Signal Timing:**
   - Dispense signal pulses high for one clock cycle when in DISPENSE state
   - Change value is valid simultaneously with dispense signal
   - Both outputs return to zero when returning to IDLE state
4. **Amount Accumulation:**
   - Internal total_amount register correctly tracks coin insertions
   - Amount updates occur synchronously with state transitions
   - Automatic reset to zero after dispensing operation

3.3 Verification Results in Table Format

Test Case	Input Sequence	Expected Outcome	Actual Result	Status
Reset Test	Reset = 1	State = IDLE, All outputs = 0	State = IDLE, Dispense = 0, Change = 0	✓ PASS
Exact Payment (25)	coin25 = 1	Dispense = 1, Change = 0	Dispense = 1, Change = 0	✓ PASS
Multiple Coins (5+10+10)	coin5, coin10, coin10	Dispense = 1, Change = 0	Dispense = 1, Change = 0	✓ PASS
Overpayment (10+25)	coin10, coin25	Dispense = 1, Change = 10	Dispense = 1, Change = 10	✓ PASS
Insufficient Funds	coin5, select	No dispense	Dispense = 0	✓ PASS
Manual Selection	25 units + select	Dispense = 1	Dispense = 1, Change = 0	✓ PASS
Reset During Transaction	Coins + reset	Return to IDLE, lose coins	State = IDLE, Amount = 0	✓ PASS
Sequential Coins	5×coin5	Dispense = 1, Change = 0	Dispense = 1, Change = 0	✓ PASS

Critical Verification Points:

1. **Functional Correctness:** All coin combinations produce expected results
2. **Timing Accuracy:** State transitions occur at correct clock edges
3. **Change Calculation:** Mathematical accuracy verified for all overpayment scenarios
4. **Error Handling:** Reset and insufficient funds cases handled properly
5. **State Machine Integrity:** No undefined states or transition errors observed

3.4 Conclusion and Future Scope

Project Conclusion:

This vending machine design successfully demonstrates the practical application of Finite State Machine principles in creating a functional digital system. The implementation achieves all primary objectives while maintaining simplicity and educational value. The design effectively handles various real-world scenarios including exact payments, overpayments, insufficient funds, and system resets.

Key Achievements:

- **Robust FSM Design:** Six-state machine handles all transaction scenarios
- **Accurate Calculations:** Precise change computation for all input combinations
- **Hardware Efficiency:** Minimal resource usage with optimal state encoding
- **Comprehensive Verification:** 100% test case success rate with thorough coverage
- **Educational Value:** Clear, well-commented code suitable for learning and demonstration

Design Strengths:

- **Modularity:** Clean separation of concerns with distinct always blocks
- **Reliability:** Comprehensive error handling and default case coverage
- **Maintainability:** Parameter-based design allows easy price modifications
- **Scalability:** Foundation supports extension to multiple products
- **Documentation:** Extensive commenting facilitates code understanding

Future Scope and Possible Extensions:

1. Multiple Product Selection:

- Implement product inventory array with individual prices
- Add product selection inputs (buttons for different items)
- Extend state machine to handle product-specific pricing
- Include sold-out detection and alternative product suggestions

2. Enhanced Error Handling:

- Add timeout mechanisms for incomplete transactions
- Implement coin jam detection and recovery procedures
- Include maintenance mode for service operations
- Add transaction logging for audit purposes

3. Low-Power Optimization:

- Implement clock gating for unused modules
- Add sleep mode during idle periods
- Optimize state encoding for reduced switching activity

TEJAREDDY

- Include power monitoring and management features

4. Advanced User Interface:

- Integrate LCD display controller for user feedback
- Add sound generation for transaction confirmation
- Implement LED indicators for system status
- Include keypad interface for PIN-based transactions

5. Communication Capabilities:

- Add UART interface for remote monitoring
- Implement wireless connectivity for inventory updates
- Include payment processing for card transactions
- Add network capability for centralized management

6. Security Enhancements:

- Implement coin validation algorithms
- Add encryption for transaction data
- Include tamper detection mechanisms
- Implement secure firmware update procedures

7. Advanced Features:

- Multi-currency support with exchange rate handling
- Temperature and environmental monitoring
- Predictive maintenance scheduling
- Customer behaviour analytics and reporting

This project provides a solid foundation for understanding embedded system design principles and can be extended into a comprehensive commercial vending machine controller with minimal modifications to the core architecture.
